WHAT IS BIOIMPEDANCE?

Bioimpedance is a measurement of how the cells in our body impede the flow of electric current. Otherwise, bioimpedance is about the electrical properties of biomaterials that are special conductors. Animal and human tissue consists of cells. The cell has a membrane, that is thin but has high resistivity and in terms of electricity behaves as small capacitor. The membrane surrounds the intracellular liquid consists from water, biological ions, enzymes, acids etc. In practice we using high frequency current which is able to pass through cell`s membrane capacitor. Direct and low frequency alternative currents cannot to pass through living cells. So, the current transition is dependent then on tissue and quality of liquids both inside and outside the cells.

WHAT IS THE PURPOSE OF MEIK MAMMOGRAPH?

Eletrical impedance computer mammograph MEIK ® is intended for mammary gland screening by means of eletrical conductivity distribution pattern visualization with the software to identify different changes in tissue structure of breast, pathologies such as cancer, cysts, scars, calcificates, fibroadenomas, mastitis, etc.

WHAT IS THE SAFETY CLASS OF THE DEVICE?

Electrical safety class: Russia…….. II,
EU…… IIa,
Canada…… II
Class of laser hazard for the sight……..…1
Weight of the unit with sensors, max……. 2 kg

CAN YOU TELL US SOME TECHNICAL PARAMETERS?

Electroimpedance computer mammograph MEIK® version 5.6 consists of:

- a microprocessor unit
- a probe cable

Microprocessor unit, controlled by the MEIK Software 5.6, is connected via a USB 2.0 port to a PC.

Power supply of a microprocessor unit …… 5 V,
Power, max ……. 400 mA,
Current used for breast scanning…… 0.5 mA,
Scanning current frequency…….. 50 kHz.

The array of microprocessor unit contains 256 cylindrical electrodes plated with galvanic gold (thickness - 2 micrometers). Gold coating allows stable contact and constant low resistance for the passage of electrical current during the stated period of operation of the device. In the middle of the

array there is a laser light that allows precise positioning of the microprocessor-based sensor on the breast.
Patient's coupling cable is fitted with push-button latches to attach self-adhesive EKG gel electrodes. This provides a stable contact with the skin of the patient during scanning.

Continuous work time: min. 8 hours,
Warranty: 2 years,
No-failure operation (ageing of electronic components), min: 10 000 hours

IS MAMMOGRAPH MEIK® A MEASUREMENT DEVICE?

Mammograph MEIK version 5.6 is not a measurement tool, but a device which operates with the calculated values of average relative conductivity of tissue, defined according to the potentials measured on the skin surface. Mathematical processing of data allows for reconstruction of seven computed tomographic slices up to 5 cm depth.

RESISTANCE AND NOISE IN MEASUREMENT, DEPTH OF SCANNING

The selected scanning current frequency (50 kHz) is optimal, because it allows to conduct examination of the skin which is moistened with tap water and does not require any special solutions with electroconductive additives. The electronic circuitry and software helps to reduce the level of external interference (noise) to less than 1%. However, **it is not recommended** to operate the device **close to powerful sources of electromagnetic radiation, because it can cause malfunctioning of the device or of the master computer.**

WHO MAKES THE CONCLUSION – THE OPERATOR OF THE DEVICE OR IS IT DONE AUTOMATICALLY BY THE SOFTWARE?

Oncomarkers embedded in the software allow the doctor to quickly and easily diagnose early forms of breast cancer.

WHAT IS THE APPLICATION OF THE DEVICE?

Oncology, mammology, obstetrics and gynecology, paediatrics

INDICATIONS FOR APPLICATION

— Evaluation of palpable lesions of the mammary gland.
— Evaluation of the impalpable changes which are not manifested clinically.
— Formation of groups of people with heightened risk of breast cancer development, using the percentile curves of the age-related electrical conductivity.
— Screening for oncopathologies.
— Additional examination of the dense tissue of the mammary gland.
— Examination in the age group under 50, including adolescents.

— Examination of pregnant and lactating women.
— Monitoring during hormonal contraception and hormone replacement therapy.
— Monitoring after pharmacotherapy or operative therapy.
— Examination of the women after cosmetic surgery.

HOW IS THE EXAMINATION OF THE BREAST DONE?

Positioning of the device

The examination is carried out on the massage couch, the patient lying on her back. Patients with small mammary glands may also be examined while sitting.

The mammary gland visualization will be shown in 7 levels from frontal point of view. To achieve this, the patient's arm nearest to the examined breast is raised, her hand placed behind her neck. The nipple must be in the center of the array with 256 electrodes.

The breast is to be moistened with a wet cotton wool tampon. Formation of droplets should be avoided.

Put disposable gel electrodes at the forearm of the opposite arm. The arm should not be touching the patient's body.

The panel with electrodes is placed against the breast in such a way that the laser light is positioned on the nipple. It is necessary to achieve the state with as little number of poor contacts as possible (good contact areas are colored green).

WHAT ARE ADVANTAGES OF MEIK?

The advantages of MEIK compared to ultrasound

- MEIK meets all the requirements of screening.
- MEIK provides complete images of the breast
- MEIK generates a tomographic image of the breast.
- MEIK provides numerical evaluation and representation of the mammary gland with the help of electrical conductivity index.
- There are oncomarkers employed in MEIK to ensure early diagnostics of breast cancer.
- MEIK is a portable device which requires minimum consumables.

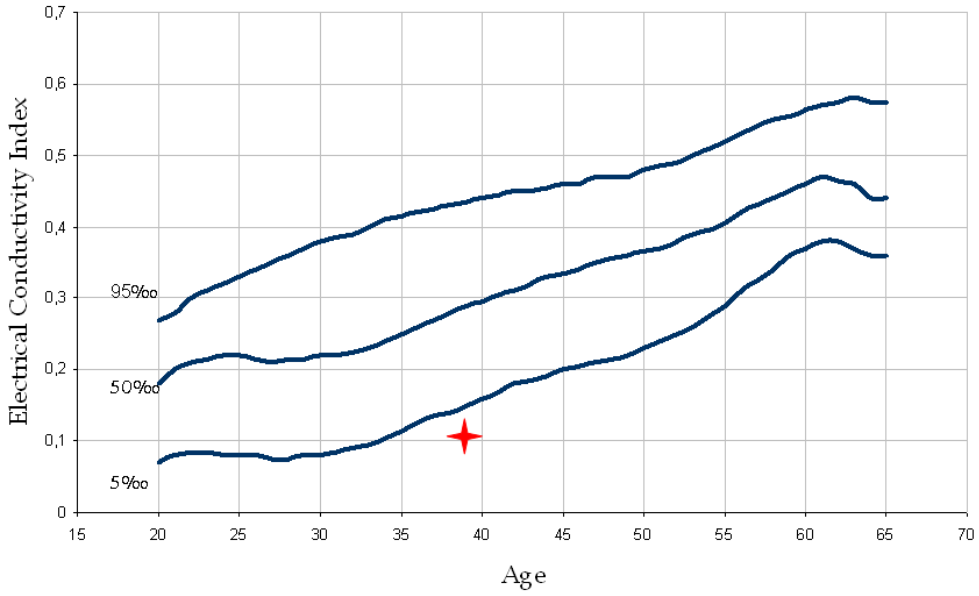
CAN MEIK DISTINGUISH BETWEEN BENIGN AND MALIGNANT TUMOURS?

Surely, since electrical conductivity of breast cancer at early stages is twice as high as electrical conductivity of benign tumours (such as cysts and fibroadenomas).

QUESTION CONCERNING LOCAL PHENOTYPE DATABASE

Creation of a local database in different phenotypes will help to develop percentile curves of age-related electrical conductivity. This would allow for primary prevention of breast cancer, namely for high risk group formation.

World Health Organization defines screening as the presumptive identification of unrecognized disease or defects by means of tests, examinations, or other procedures that can be applied rapidly and for large population groups.



Percentile curves of age-related electrical conductivity of the mammary gland. Electrical conductivity index (red marking) is lower than age norm (<5‰).

It is reasonable to develop such tests, which do not require high-skilled experts, though widely use computer aids and application software. Nowadays the pre-clinical diagnostic criteria, which are acquired after statistical processing of great diagnostic information array and enable to determine high-risk cancer groups among the patients, become more and more important.

The groups of people with heightened risk of breast cancer development can be formed with the help of the percentile curves of the age-related electrical conductivity. The usage of percentile curves is habitual for many diagnostic techniques. For example, ultrasound specialists widely use percentile curves to assess growth and development of the fetus. The figure shows the percentile curves of age-related electrical conductivity, where each age group corresponds to a certain range of electrical conductivity. The values which fall into the first range (less than 5th percentile) should be considered as pronouncedly low and the values which fall in the fourth range (above 95th percentile) - as pronouncedly high. Patients with anomalously low age-related electrical conductivity of the mammary gland (less than 5th percentile, indicative of high density of ductal component) shall be considered as belonging to the high-risk group. High density of ductal component is potentially dangerous as it can be accompanied by insufficient trophic function of the connective tissue. It is well known that this function is performed by inoglia mainly. Dyscrasia may lead to dystrophic processes, in the basal membrane as well.

WHAT IS THE PRINCIPLE OF OPERATION?

Currently, a variety of electrical impedance diagnostic systems is used both in academic studies and in clinical practice. A significant part of such systems employs electrodes which reside in a single array and two-dimensional mathematical conductivity reconstruction algorithms in the array of the electrodes. Electrical impedance mammograph belongs to the class of 3D tomography systems.

Thus, all the measurements are made on the surface of the investigated object. The change of surface potential difference (compared with the homogeneous case), as a rule, is caused by the presence of a local heterogeneous area in the object. It is mainly concentrated in the area which is a projection of the local heterogeneous area on the surface of the object.

Therefore, the main objective of electrical impedance mammography is to visualize the reconstructed three-dimensional electrical conductivity distribution of the object, basing on the results of electrical measurements on its surface.

For this purpose various modifications of mathematical method of “back projection” are employed (Dunaeva O.; Gerasimov D., Karpov A., Machin M., Tchayev A., Tsofin Yu., Tsyplyonkov V. Using Backprojection Algorithm for 3D Image Reconstruction in EIT. *World Congress on Medical Physics and Biomedical Engineering*, Munich, Germany, 2009). Mathematical methods provide also cross-sectional slices of conductivity.

AT WHICH MARKETS IS MEIK USED GLOBALLY?

MEIK mammograph is used worldwide, namely in: Russia and CIS countries, countries of European Union, Croatia, Turkey, Malaysia, Indonesia, Hong Kong, South Africa and Australia. Currently, it is being registered in Canada and South Korea.

IT IS POSSIBLE TO MAKE EARLY DIAGNOSTICS OF BREAST CANCER?

In majority of medical research statistical diversion validation criteria are calculated to validate the diagnostic significance of a test. However, these criteria are not enough. If the method of diagnostics under examination permits to acquire a numerical result, the so-called "breaking point" (the value exceeding of which is considered as a sufficient cause for qualitative assessment) should be determined. In this case the estimation of diagnostic technique efficiency may be limited to sensitivity and specificity assessment.

The diagnostic criterion when screening for early stages of breast cancer (the dimensions of a tumour less than 1 cm) is the following: high electrical conductivity areas (above 0.95 cu) outside the lactiferous sinus zone – the so-called animpedance areas, which differ markedly from electrical conductivity of healthy mamma’s areas. It seems that membrane permeability increase is necessary in both directions to support vital activity of dedifferentiated cells during the intraductal stage of oncologic process. The membrane permeability of cancer cells during intraductal and early extraductal stage increases both for chemical compounds and electric charges. This process results in increase of electrical conductivity.

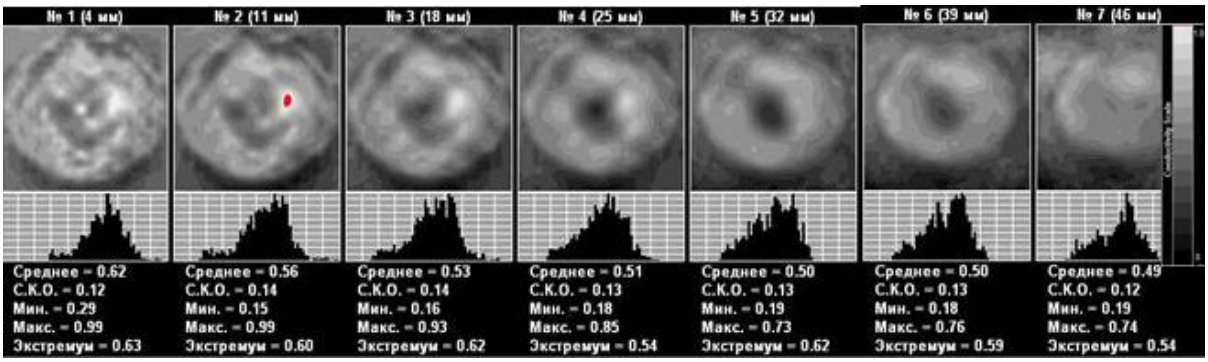


*Fig. **1.** EIM. Amorphous type of mammary gland structure. In the outer segment of the left mammary gland, at 3 o'clock position there is observed an an-impedance area, which is highlighted with red in the second scan plane, less than 10 mm in size.*

The example of electrical impedance diagnostics. Figure 1 represents the electrical impedance mammogram of a patient. There can be distinguished a focal lesion, in the form of an-impedance area, highlighted with red, with electrical conductivity index over 0.95 conditional units. This is the criterion for early diagnostics of breast cancer. Roentgenogram and US image of the same mammary gland are represented below (Fig. 2, 3).

Fig. 2. Roentgenogram: Fibro-fatty involution. In upper-outer segment there is observed a lesion up to 1 cm in size with a radiant contour.

Fig. 3 Ultrasound: The structure of parenchyma with adipose lobules and connective tissue layers. An inhomogeneous 8x7 mm lesion of irregular shape is located at 28 mm distance from the nipple and at 12 mm depth.

With such a breaking point the sensitivity and specificity of electrical impedance mammography are quite high: sensitivity is 84-93%, specificity – 87-99% (according to data issued by different authors).

WHICH STANDARDS WERE USED IN REGISTRATION PROCESS?

LIST OF STANDARDS

Rules and Regulations applied during the design and manufacture of MEIK
